1. Text Classification
2. Regularization Techniques
3. Discussion

- Text classification is a classical topic in Natural Language Processes, e.g., spam filtering, sentiment analysis, DA, RA, intent models, ...
- Two components: Sentence representation and classification

Sentence embedding

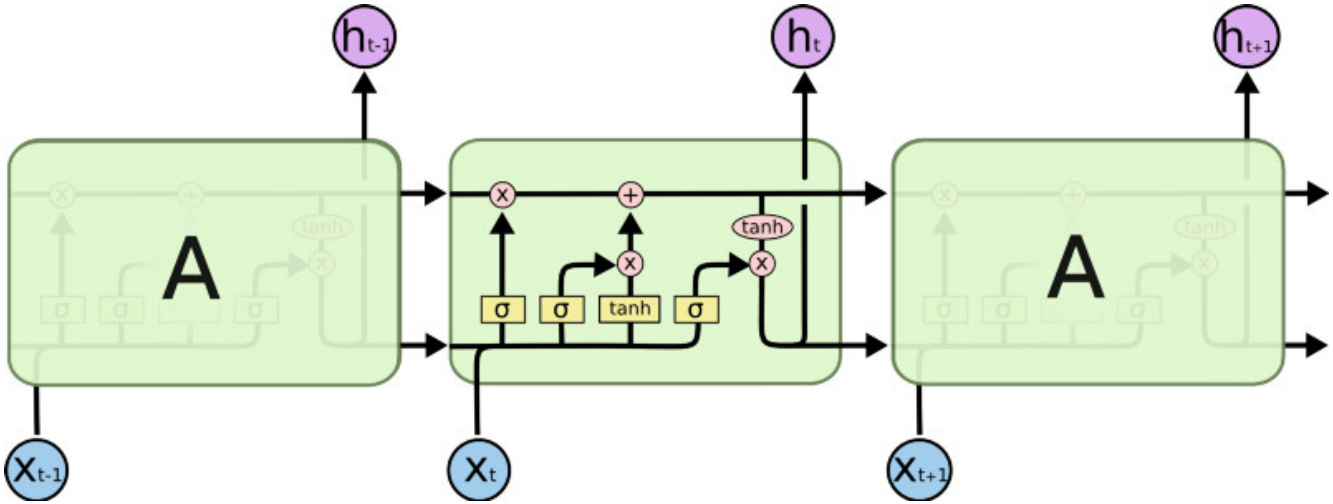
Traditional Methods:

- Bag of words and its TFIDF (term frequency-inverse document frequency)
- Bag of ngrams and its TFIDF

Deep Learning:

- Word-based ConvNets
- Character-based ConvNets
- *LSTM*

LSTM



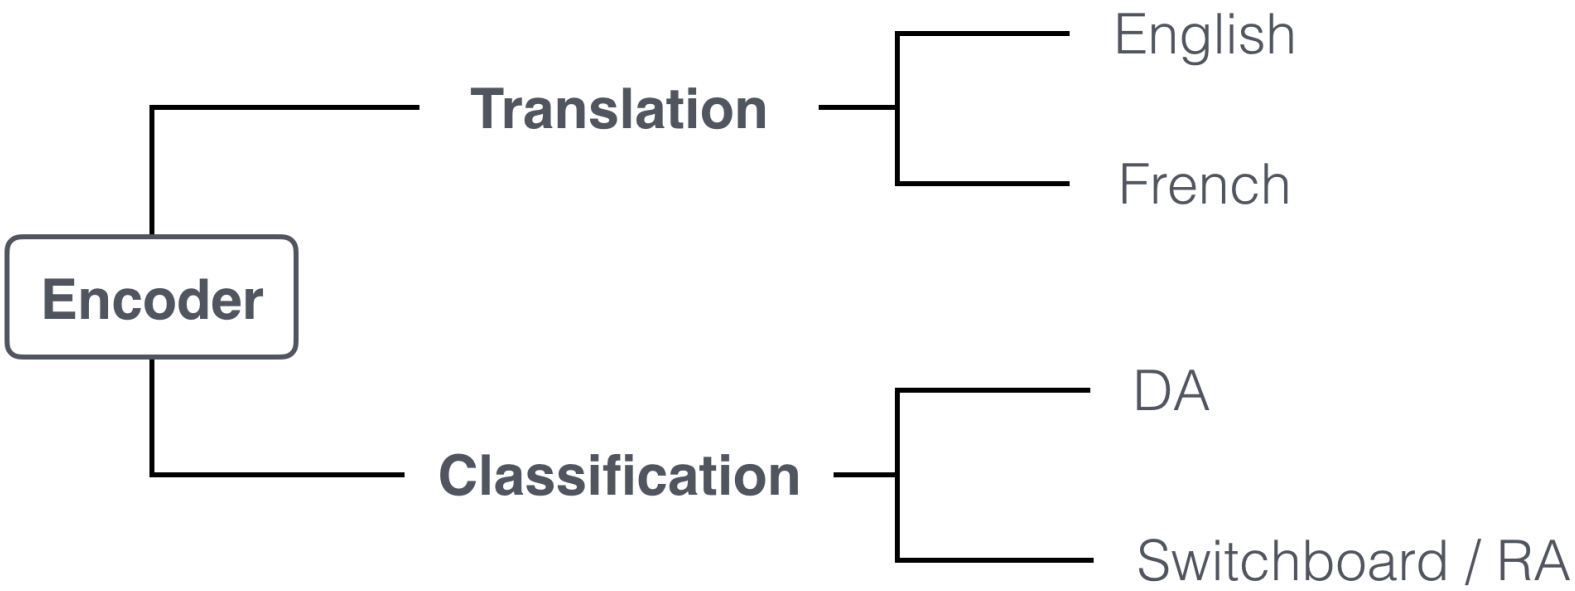
- *Use the last state as the sentence representation*
- Use the average of the states as the representation (not yet implemented)

Regularizations

DA-movie has 8.5k training data and 1k validation data. The dimension of Glove embedding is 300 and hidden state's dimension is 256. Overfitting is an obvious problem. Standard regularization techniques:

- early stop
- dropout
- label smoothing
- ridge/lasso
- multitask learning

multitask learning



Discussion

Possible future directions:

- ensemble
- try different classifier, for example SVM
- use the mean of the hidden state instead of the last state
- add more features

Discussion: how much data do we need?

It is difficult to predict the learning curve

- VC dimension provides a theoretical bound, which is useless in this case.
- Depends on a lot of factors:
  - classification method
  - complexity of the classifier
  - how well the classes are separated
  - data quality
  - ...

Dataset used by LeCun et al. (Character-based ConvNet)

Dataset	Classes	Train Samples	Test Samples	Epoch Size
AG's News	4	120,000	7,600	5,000

Some thoughts on DA and RA

Given the DA label and RA label are correlated (YK's result suggested: Using DA label as feature improves RA's result. And vice versa), possible improvement

- On test time iteratively using DA prediction and RA prediction.
- Change the structure of the graph, e.g.,

Thank you
